

Connection Repository

Connection repository integrates with the spring data repository. This enables your application to lookup based on either the destiny or the originating DataEntry.

Definition

```
@Repository
public interface AuthoredConnectionRepository
    extends NDBConnRepository<AuthoredConnection, String, BookDE, AuthorDE>{

}
```

This Repository definition contains not only the Connection (AuthoredConnection) but also the originating DataEntry (AuthorDE) and the destination DataEntry (BookDE).

Usage

```
@RestController
public class AnimeController{

    @Autowired
    AuthorDataRepository authorRepository;

    @Autowired
    AuthoredConnectionRepository authoredConnectionRepository;

    @GetMapping("/authored/{name}")
    public Set<AuthoredConnection> getByName(@PathVariable String name){
        Optional<AuthorDE> byName = authorRepository.findByName(id);
        if(byName.isPresent()){
            return authoredConnectionRepository.getByFrom(byName.get());
        }
    }
}
```

```

        return null;
    }
    @DeleteMapping("/authored/{name}")
    public void deleteByName(@PathVariable String name){
        Optional<AuthorDE> byName = authorRepository.findByName(id);
        if(byName.isPresent()){
            authoredConnectionRepository.getByFrom(byName.get()).foreach(authored->
            authoredConnectionRepository.delete(authored));
        }
        return null;
    }
    @UpdateMapping("/authored/{name}/{country}")
    public void updateCountryByName(@PathVariable String name, @PathVariable String country){
        Optional<AuthorDE> byName = authorRepository.findByName(id);
        if(byName.isPresent()){
            authoredConnectionRepository.getByFrom(byName.get()).foreach(authored->{
                authored.setCountry(country);
                authoredConnectionRepository.save(authored);
            });
        }
        return null;
    }
}

```
